Kaszkowski, Z.

TITLE:

Effect of heat-treatment on Q-factor of Ni-Span C type alloys

PFRIODICAL: Referativnyy zhurnal, Metallurgiya, no. 10, 1962, 19, abstract 10I127 ("Bull. Acad. polon. sci. Sér. sci. techn.", v. 10, no. 1, 1962, 51 - 55, English; summary in Russian)

TEXT: The results are cited of an investigation of Q-factor and of the temperature coefficient of mechanical resonance frequency of two Ni-Span C alloys depending on the heat treatment. The samples were preheated to 1,000°C during 1 hour in H2 atmosphere and then water quenched. After that the samples were annealed at 500, 600, 700; 600 and 900°C with a subsequent water quenching. Q was measured at room temperature in the air and in a vacuum. Curves with Q plotted against the annealing temperature are presented. For one of the samples after annealing at 600° C, Q = 3,900 in a vacuum and Q = 26,000 in the air. The temperature coefficient of resonance frequency after a certain heat-treatment (annealing at 540 and 860°C) is very low or equal to zero in the temperature range of 20 - 60°C.

Warsaw-Lublin, Medycyna Weterynaryjna, Vol 18, No 11, Nov [Authors' English summary modified] Experimental Abstract: [Authors' English summary modified] Experimenta procedures are given for paisoning and determinations. In 62. pp 646-650. procedures are given for personing and departmentations, and postmortem and histological examination the following changes were found: Strong hypersemia of bloodyessels and oedema of were jound; Strong hyperments of microuressets and decima of meninges and corebral cortex, conters of softening in deeper levere particularly the transfer of softening in deeper levere particularly the second sec layers particularly of the temporal and pariotal lobes, and proliferation of colls of the microglic. The meningo encephalitis eosinophilica, typical for common salt peisching, was observed in only one pig. 14 references: 3 English, 3 Polish, and 2 German.

Abstract: [Author's English summary modified] Cooling $(-1.2-5^{\circ}C)$ for a period up to 21 days caused in 5 out of 13 experimental pigs, after exposure of 2-5 days, a sensory-motoric syndrome, which the author calls spinal shock, consisting of paresis of the limbs, lowered muscle tonus, disturbances of equilibrium, and hypersensitivity to pain and touch. The symptoms were transitional and disappeared 2--3 weeks after cooling ceased. Histological examination revealed that the underlying cause was injury to the spinal cord as the result of small hemorrhages mainly in the lumbar and sacral segments. 22 refs, with 2 Soviet.

TITLE:

The Causes of Uncontrolled Flap Protraction and Canopy Lock

Release

PERIODICAL:

Wojskowy przegląd lotniczy, 1959, Nr 12, pp 12-15 (POLAND)

ABSTRACT:

The author describes the causes of uncontrolled flap protraction in taxing aircraft as well as uncontrolled canopy lock release. He explains that flap protraction (as much as the maximum 55° with the flap seperator lever in the 20° position) is caused either by shocks of taxing on rough strips or by deficiencies in the retracting jack. The weight of a flap pulls on the jack piston with a force of about 16-18 kg and is resisted by friction and decompression forces in the cylinder totaling about 20-30 kg. The overload coefficient for taxing shocks may be as high as 2.6-3.5, and multiplied by the flap weight force of 15 kg makes for an overload force of at least 39 kg. This force considerably exceeds the friction and resistance forces in the cylinder and causes uncontrolled protraction of the flap. Another

Card 1/3

POL/44-59-12-4/36

The Causes of Uncontrolled Flap Protraction and Canopy Lock Release

reason is leakage in the retracting jack system which, most frequently, is due to damaged piston gaskets. For a tightness test, the landing gear distributor lever is positioned "neutral", the aerodynamic brake distributor lever "retracted", and the flap retraction system tested under pressure with the flap distributor lever positioned "neutral", "protracted 200", "protracted 550" and "retracted" respectively. As the automatic discharge valve sets in, pressure and time are recorded. The starting pressure usually is 135-140 atmospheres, the end pressure 85 atmospheres. The lever is kept in the neutral position for 8 minutes, in all other positions for 5 minutes. If pressure drops below 85 atmospheres after 8 and 5 minutes respectively, the system must be closely checked. Further, the author describes the causes of canopy lock releases, which mostly are due to faulty maintenance. As an example he states that if the guide hinge of the canopy (Diagram 1, item 1) is set into locked position while the control and lock levers (Diagram 1, items 2 and 3) are not positioned to coverage of the lock marks, an uncontrolled release of the

Card 2/3

POL/44-59-12-4/36

The Causes of Uncontrolled Flap Protraction and Canopy Lock Release

canopy might occur. According to instructions, the control lever roller must pass under the upper end of the lock bar (Diagram 1, item 4) not less than 3 mm. If a canopy release occurs when locks are fastened and levers slightly touched, the reason is improper setting and lack of air in the rubber packing hose, due to a deficiency in the plate valve of the pneumatic tightening system (Diagram 2), which in turn is caused by low elasticity of the spring controlling a segment of the plate valve. Finally, the author points out that careful examination of canopy locks by the pilot before take-off ensures timely detection of oversights. There are 2 diagrams.
